Larkspur dispatch policy

OPS-09 revision 3. Issued 12 November 2026 at 09:00 UTC.
Owner: Mara Ives, operations director. All names and data are fictional.

1. Release scope and authority

Plan only the Friday 13 November 2026 release. The decision cutoff is Thursday 12 November at 14:00 UTC. Treat everything as it was known at that instant, even though the database export was assembled at 14:20. All timestamps and wave names are UTC. Friday 12:00 and Friday 16:00 are the only dispatch waves. Later waves, overtime, purchases, substitutions and warehouse transfers are unavailable.

This policy and the current database replace operational assumptions in the 11 November launch briefing. The briefing remains background and customer context only. A sent approval from Mara before the cutoff may override only the exact constraints it names. Drafts, forecasts and records first received after the cutoff cannot authorize a plan. Keep any unapproved proposal out of the executable plan.

2. Point-in-time reconstruction

A record is known only if BOTH effective_at and recorded_at are at or before the cutoff. Apply this to inventory events, order events and reservation events. For ORDER and RESERVATION STATUS histories, the last known effective event wins, using recorded_at and event_id in ascending order to break equal effective times. With no known status event, use the row's initial status. Physical inventory adjustments instead add together under the snapshot rule below.

For each warehouse, choose the most recent COMPLETE inventory snapshot with as_of and recorded_at at or before the cutoff. Every snapshot contains all five SKUs. A newer snapshot REPLACES an older snapshot. It already includes physical events through its as_of time. To get gross usable stock, add only inventory events whose effective_at is strictly after that snapshot, whose effective_at and recorded_at are known, whose status is POSTED, and whose kind is RECEIPT, SCRAP or QUARANTINE. Negative deltas are already signed. FORECAST and VOID rows never affect physical stock. Quarantine deltas already remove unusable units: do not subtract them again.

Reservations are separate commitments for unrelated work and are NOT already deducted from the physical snapshots. Subtract every component line of each reservation whose reconstructed status is ACTIVE. A release entered after the cutoff is unknown even if it claims an earlier effective time. These are not reservations for the candidate orders, so shipping a candidate never consumes or frees a reservation. Unreserved usable stock is the release budget.

Assembly and dispatch limits

3. Complete kits and orders

All candidate order quantities and status baselines are in orders. Apply order_events using section 2. Only READY orders may ship. Each order is indivisible: ship its exact full quantity from one warehouse in one wave, or defer the entire order. No partial shipment, mixing warehouses or waves within an order, unlisted products, loose components or BOM substitutions. Every kit uses one carton.

Kit	CORE	SENSOR-A	SENSOR-B	BATTERY	PACK	Assembly minutes / kit
Scout	1	2	0	1	1	3
Relay	1	0	1	2	1	4

The bom and kit_labor tables repeat these approved rules for calculation. All component quantities are whole units. Assembly can start Friday morning using only the release budget reconstructed at the cutoff. No future receipt becomes available in either wave.

4. Capacity and carrier cutoffs

Warehouse	Assembly minutes by 12:00	Total Friday assembly minutes	12:00 cartons	16:00 cartons
North	24	50	10	12
South	20	38	8	10

The capacity table repeats these limits. Early-wave assembly minutes count toward the SAME daily total, not an additional allowance. Late work may use the remaining daily capacity. Carrier carton limits are separate per wave and do not carry over. Do not move assembly effort or carton space between warehouses. Kits for the early wave must fit that warehouse's early assembly limit.

An order normally uses its home_warehouse. Its dispatch wave must be no later than latest_dispatch_utc: a 12:00 order cannot use 16:00 without a specific approval. A 16:00 order can use either wave. A sent exception may introduce a narrowly scoped alternative. It does not remove component, daily assembly or carrier limits unless it explicitly says so.

5. Choice of plan

Choose a feasible plan that first maximizes the SUM of priority_points for fully shipped orders. These are points PER ORDER, never per kit. Among plans with the same maximum points, maximize the SUM of contribution_usd for shipped orders. Contribution is USD PER COMPLETE ORDER, not per kit. There is no further tie-break: any assignment of waves with the same optimal order selection and totals is acceptable if feasible. Do not claim that a greedy ordering alone proves optimality. Show a reproducible enumeration, a concise upper bound, or another checkable justification.

This is planning only. Do not send email or modify the source database. All feasible full-order allocations may be considered, including those not suggested in the old briefing.
